LL ZL, 0782765812

as USGS hydrologist, I
was ordered to drive there to conduct a survey -
example, hydrology, estuarine processes, tides -
and around the area where the proposed dam
would be built. During the survey, I found
that - probably because USSR's lack of experience
with dams, they had not yet developed a
method for predicting the effects of such a
dam on the river system. This was a major
problem, as it would affect the entire river
system, including the entire basin, which
is about 100,000 km².

After consulting with my colleagues at USGS, I
decided to use a method developed by the
University of California, Berkeley, called
the "Bathymetric Method". This involved
measuring the water level in various parts of
the river system and then using a computer
program to calculate the volume of water in
each part of the system. This information
was then used to predict the effects of the
dam on the river system, including the
entire basin, which is about 100,000 km².
